FEB 2019

ABSTRACT

The longline CPUE series for Inaccessible and Gough islands are GLMM standardised through to 2018¹. For Nightingale, the fishery was closed for the 2011 season and catches were set at precautionary levels for the 2011 and 2012 seasons. The Nightingale GLMM model thus excludes 2011 and 2012, although it now includes 2013-2018 for this island. Year, month, area, trap-type, soak time, depth and year-area interactions are treated as fixed effects, and year-month interactions treated as a random effect. The standardised CPUEs for Inaccessible and Nightingale continue to be optimistic, although both show slight decreases since the previous season. For Gough, the standardised CPUE value for the current season is higher than that of the previous season.

INTRODUCTION

The commercial CPUE series of a resource is often used as an index of population density and consequently to inform on population abundance when modelling the dynamics of the underlying population. It is known, however, that a number of other factors besides density may influence the recorded values of CPUE. Where sufficient data exist, General Linear Mixed Model (GLMM) standardisation is able to take some of these further effects into account, thereby producing a more reliable index of abundance. This document reports the application of a GLMM standardisation to *Jasus tristani* lobster catch per unit effort data from around Inaccessible and Gough Islands for the period 1997-2018, and for the period 1997-2018 omitting seasons 2011 and 2012 for Nightingale (whose fishery was closed in the 2011 season due to the grounding of the OLIVA in March 2011, and where only precautionary catch levels have been set instead of TACs for 2012 and 2013). Results presented here are updated from those presented in Johnston *et al.* (2016), taking two more year's data into account.

¹ The convention used here for split seasons is to use the first year, i.e. 2013 refers to the 2013/2014 season.

METHODOLOGY

Data

Raw Logsheet data

The logsheet data for the outer islands have been entered electronically into EXCEL spreadsheets. Logsheet data from the fishery are available for the Season-Years between 1997 and 2018, where a Season-Year is taken to run from September until August of the following year, i.e. Season-Year 2005 refers to the period from September 2005 to August 2006. (The fishery around each of these islands will conclude well before August 2019 for the 2018 season.)

The General Linear Mixed Model

A GLMM which includes both fixed and random effects is used to standardise the lobster CPUE data for the three outer islands, where catches are the logsheet retained catches and effort is logsheet effort. (Note that this approach assumes that the logsheet data represent an unbiased sample from all the fishery in each Season-Year.) This model allows for possible annual differences in the areal distribution of the lobsters (which is considered to be a fixed effect) and for annual differences in each month (considered as a random effect). The model is given by:

$$\ln(CPUE + \delta) = \mathbf{X}\alpha + \mathbf{Z}\beta + \varepsilon \quad (1)$$

where:

α	is the unknown vector of fixed effects parameters (in this case this consists of the factors given by equation (2) below),
\mathbf{X}	is the design matrix for the fixed effects,
β	is the unknown vector of random effects parameters (which in this application consists of a year-month interaction),
\mathbf{Z}	is the design matrix for the random effects,
δ	is a small constant added to the rock lobster CPUE to allow for the occurrence of zero CPUE values (0.1 kg/trap in this case, being about 10% of the average nominal values), and
ε	is an error term assumed to be normally distributed and independent of the random effects.

This approach assumes that both the random effects and the error term have zero mean, i.e. $E(\beta)=E(\varepsilon)=0$, so that $E(\ln(CPUE+\delta)) = \mathbf{X}\alpha$. The variance-covariance matrix for the residual errors (ε) is denoted by \mathbf{R} and that for the random effects (β) by \mathbf{G} . The analyses undertaken here assume that the residual errors as well as the random effects are homoscedastic and uncorrelated, so that both \mathbf{R} and \mathbf{G} are diagonal matrices given by:

$$\mathbf{R} = \sigma_{\varepsilon}^2 \mathbf{I}$$

$$\mathbf{G} = \sigma_{\beta}^2 \mathbf{I}$$

where \mathbf{I} denotes an identity matrix. Thus, in the mixed model, the variance-covariance matrix (\mathbf{V}) for the response variable is given by:

$$\text{Cov}(\ln(CPUE + \delta)) = \mathbf{V} = \mathbf{Z}\mathbf{G}\mathbf{Z}^T + \mathbf{R},$$

where \mathbf{Z}^T denotes the transpose of the matrix \mathbf{Z} .

The sum of the factors that are considered as fixed effects (i.e. $\mathbf{X}\alpha$ in equation (1)) in the GLMM is given by the following:

$$\ln(CPUE + \delta) = \mu + \alpha_{year} + \beta_{month} + \gamma_{area} + \eta_{trap-type} + \lambda_{soaktime} + \theta_{depth} + \tau_{year \times area} \quad (2)$$

where

μ	is the intercept,
$year$	is a factor with 22 levels for Gough and Inaccessible associated with the Season-Years 1997-2018, and 20 levels for Nightingale associated with the Season-Years 1997-2018 (excluding 2011 and 2012),
$month$	is a factor with levels associated with the fishing month (1-12 for Gough, 1-3 and 9-12 for Nightingale, and 1-3 and 8-12 for Inaccessible),
$area$	is a factor with levels associated with groupings of fishing areas (Gough = 6 areas, Nightingale = 5 areas, Inaccessible = 9 areas),
$trap\ type$	is a factor with levels associated with the trap type (monster and bee hive),
$soak\ time$	is a factor with 3 levels associated with the soak time period (“1”=0.0–0.49 days, “2”= 0.5–1.9 days and “3” for 2 or more days),
$depth$	is a factor with 4 levels associated with fishing depth ranges (“1” for depths < 10m, “2” for 10–39.9m, “3” for 40–89.9m, and “4” for depths \geq 90 m),
$year \times area$	is the interaction between year and area.

In this application the CPUE has been standardised on the year 1998, month of *September*, trap type *Monster*, soak time “2”, depth category “2” and area = “1”.

For this model, because of the fixed effect interaction of area with year (which implies changing spatio-temporal distribution patterns), an index of overall abundance needs to integrate the different trends in density in each area over the size of these areas. Accordingly the standardised CPUE series is obtained from:

$$CPUE_{year} = \left[\sum_{area} \left(\exp(\mu + \alpha_{year} + \gamma_{area} + \tau_{year \times area}) - \delta \right) * A_{area} \right] / A_{total} \quad (3)$$

where

- A_{area} is the surface size of the area concerned,
- A_{total} is the total size of the fishing ground considered (the division by A_{total} is to keep the units and size of the standardised CPUE index comparable with those of the nominal CPUE), and
- δ is taken to be 0.1 kg/trap (about 10% of the nominal average values).

Table 1 provides the A_{area} values for Inaccessible, Nightingale and Gough Islands.

RESULTS

Table 2 provides standardised CPUE values derived from the GLMMs considered. For comparison, the nominal CPUE values are also reported. Figures 1a-c compare the nominal CPUE with the updated 2017 standardised CPUE series, along with the 2016 standardised CPUE series. The series have been renormalised to an average value of 1 over the 1997-2015 period in the plots for comparative purposes. Figures 2a-c shows the month effects and Figures 3a-c shows the area effects for each island. Figures 4a-c show the updated standardised CPUE series for each outer island, along with the current OMP Itar and Ilim values for each island.

DISCUSSION

The updated GLMM CPUE series reported are to be used to provide inputs into the OMPs for Inaccessible, Gough and Nightingale to provide TAC recommendations for the 2019 season. The GLMM CPUEs for Inaccessible and Nightingale have decreased slightly during the 2018 season compared with the previous season (Figures 4a and b), but remain well above the Itar values. For Gough, the GLMM CPUE value for the current season has increased compared with previous season (Figure 4c) and is close to the Itar value.
